ICT central bank dealers range is basically a range of price at a specific time of the day which can help you in projecting the high and low of the day in both bearish and bullish days.

Central bank dealers range is used to project the high and low of a potential trading day.

Using directional bias in conjunction with CBDR adds strength to the projections.

This blog post will let you master the ICT central bank dealers range from its identification to use in intraday trading.

You can jump to the section you are most interested in from

What is ICT Central Bank Dealers Range – CBDR?

ICT CBDR is an important central range of price ranging from 02:00 PM to 08:00 PM New-York local time. That can be replicated above or below using the standard deviation.

Now let's understand the central range and standard deviation.

Let's suppose we have a central range in the form of rectangle as shown in the picture below:

A standard deviation is a measure of how dispersed the data is in relation to the mean (center).

So, the one standard deviation above the central range will be the same range added to it as shown in the picture below.

While one standard deviation below the central range will be the same range subtracted from it as shown in the picture below.

Now the same phenomenon can be applied to price to measure its central range from **02:00 PM to 08:00 PM NY-local time**, and

its standard deviations as show in the picture below.

Ideal ICT Central Bank Dealers Range

Central bank dealers Range height can be measured using the high and low of that price range, you may use wicks to measure the height or the bodies of candlesticks, while the ICT prefers the bodies over wicks.

Ideally central bank dealers range should be less than 40 pips preferably not more than 20-30 pips.

Range larger than 40 pips would be unfruitful and, on that day, you will let price do what it wants to do except for scalp trades.

How to Use Central Bank Dealers Range in Trading?

Most **sell days** create high of the day up to 3 standard deviations above the central bank dealers range.

Ideally sell day would create high of the day no more than 2 standard deviations above the CBDR and many times it will be only one standard deviation.

While you can project the low of sell days by taking the central range and its standard deviations together as a single range and moving it down to -3 standard deviations.

And low of the day will most probably happen in **London close Kill Zone**.

A real market example of bearish day projecting high and low of the day is shown in the picture below:

While, most **buy days** create low of the day up to 3 standard deviations below the central bank dealers range.

Ideally buy day would create low of the day no more than 2 standard deviations below the CBDR and many times it will be only one standard deviation.

You can project the high of buy days by taking the central range and its standard deviations together as a single range and moving it down to -2 or -3 standard deviations depending upon the central range deviations.

And high of the day will most probably happen in **London close Kill Zone**.

A picture below depicts the real market example Central bank dealers range projecting high and low of buy day.

For complete intraday trading strategy using ICT Central Bank Dealers Range visit [ICT Intraday Profiles](#).

Best Time Frame for ICT Central Bank Dealers Range

Best timeframe to measure the ICT central bank dealers range would be the lower timeframes preferably 15 minutes or lower than that.

Best Pair for ICT Central Bank Dealers Range

The ICT Central Bank Dealers Range strategy, first developed and tested on the NASDAQ (NQ Futures) and E-mini (S&P 500), found its strength in these indices.

As traders applied it to other markets, such as forex and metals, it continued to show remarkable effectiveness.

Now, this strategy is just as powerful when used on major forex pairs like GBP/USD, EUR/USD, and XAU/USD.

Best Day to Trade Using ICT Central Bank Dealers Range

You can use ICT CBDR on every day of a week if its an ideal range of less than 40pips.

But, as the weekly high/low is expected to be formed on Tuesday or Wednesday so these days can be the high yielding days using the ICT central bank dealing range.

Can you please break down this on how you draw the central range and also zoom in the chart a bit more? I read this twice, but somehow unable to understand the concept well.

Thanks in advance
